ECE408/CS483/CSE408

Applied Parallel Programming

Lecture 5: Locality and Tiled Matrix Multiply

Course Reminders

- Lab 1 is out, it is due this Friday
- Lowest lab grade will be dropped from the final grade
 - Thus no late submissions are allowed for labs

Objective

- To learn to evaluate the performance implications of global memory accesses
- To prepare for MP3: tiled matrix multiplication
- To learn to assess the benefit of tiling

Parallel Memory Updates

```
__global__
void ThreadIncrement(int *x)
{
    // Each thread increments x
    x++;
}
```

What is the value of x if we have 128 threads in execution?

Matrix Multiplication -- Simple CPU Version

```
// Matrix multiplication on the (CPU) host in single precision
void MatrixMul(float *M, float *N, float *P, int Width)
   for (int i = 0; i < Width; ++i)
        for (int j = 0; j < Width; ++j) {
            float sum = 0;
            for (int k = 0; k < Width; ++k) {
               float a = M[i * Width + k];
               float b = N[k * Width + j];
               sum += a * b;
           P[i * Width + j] = sum;
```

MatMult Kernel: Width = 8, BLOCK_WIDTH = 4

P _{0,0}	P _{0,1}	P _{0,2}	P _{0,3}	P _{0,4}	P _{0,5}	P _{0,6}	P _{0,7}
P _{1,0}	P _{1,1}	P _{1,2}	P _{1,3}	P _{1,4}	P _{1,5}	P _{1,6}	P _{1,7}
P _{2,0}	P _{2,1}	P _{2,2}	P _{2,3}	P _{2,4}	P _{2,5}	P _{2,6}	P _{2,7}
P _{3,0}	P _{3,1}	P _{3,2}	P _{3,3}	P _{3,4}	P _{3,5}	P _{3,6}	P _{3,7}
P _{4,0}	P _{4,1}	P _{4,2}	P _{4,3}	P _{4,4}	P _{4,5}	P _{4,6}	P _{4,7}
			P _{4,3}				
P _{5,0}	P _{5,1}	P _{5,2}		P _{5,4}	P _{5,5}	P _{5,6}	P _{5,7}

Kernel Invocation (Host-side Code)

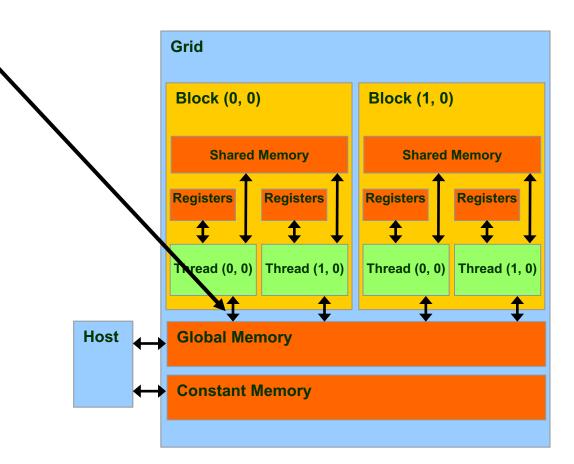

```
// Setup the execution configuration
// BLOCK WIDTH is a #define constant
dim3 dimGrid(ceil((1.0*Width)/BLOCK WIDTH),
             ceil((1.0*Width)/BLOCK WIDTH), 1);
dim3 dimBlock(BLOCK WIDTH, BLOCK WIDTH, 1);
// Launch the device computation threads!
MatrixMulKernel<<<dimGrid, dimBlock>>>(Md, Nd, Pd, Width);
```

A Simple Matrix Multiplication Kernel

```
global
void MatrixMulKernel(float *d M, float *d N, float *d P, int Width)
   // Calculate the row index of d P and d M
   int Row = blockIdx.y * blockDim.y + threadIdx.y;
   // Calculate the column index of d P and d N
   int Col = blockIdx.x * blockDim.x + threadIdx.x;
   if ((Row < Width) && (Col < Width)) {
      float Pvalue = 0;
      // each thread computes one element of d P
      for (int k = 0; k < Width; ++k)
          Pvalue += d M[Row * Width + k] * d N[k * Width + Col];
      d P[Row * Width + Col] = Pvalue;
```

How about performance on a device with 150 GB/s memory bandwidth?

- All threads access global memory for their input matrix elements
 - Two memory accesses (8 bytes) per floating point multiply-add (2 fp ops)
 - 4B of memory for each FLOP
 - 150 GB/s limits the code at 37.5 GFLOPS
- The actual code runs at about 25 GFLOPS
- Need to drastically cut down memory accesses to get closer to the peak of more than 1,000 GFLOPS

Avoid the BW Bottleneck by exploiting Reuse

- Each element of M and N is used Width times in calculating P
- To avoid BW limitations, exploit data reuse by leveraging the per SM shared memory

Partition data into tiles that fit into the shared memory

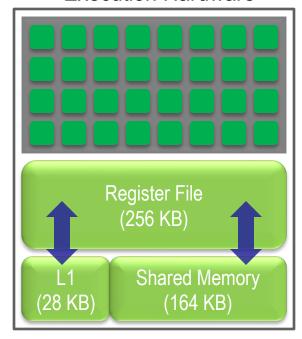

- Each thread block uses the following strategy:
 - Load the tile from global memory to shared memory
 - Perform the computation on the tile from shared memory; each thread can efficiently access any data element
 - Copy the result from shared memory to global memory

Shared Memory Tiling Basic Idea

Data in Global Memory Thread 2 Thread 1 Data in Global Memory Shared Memory Thread 1 Thread 2

SM Memory Architecture

Execution Hardware

SM Memories (Shown for an Ampere-class GPU)

- registers (~1 cycle)
- shared memory (~5 cycles)
- cache/constant memory (~5 cycles)
- global memory (~500 cycles)

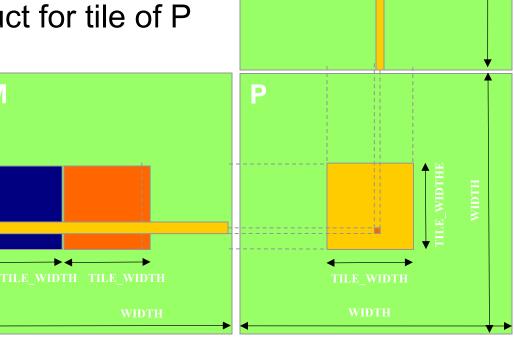

Declaring Shared Memory Arrays

Outline of Technique

- Identify a tile of global data with high data reuse
- Load the tile from global memory into shared memory
- Threads in the block access their data from shared memory
- Move on to the next block/tile

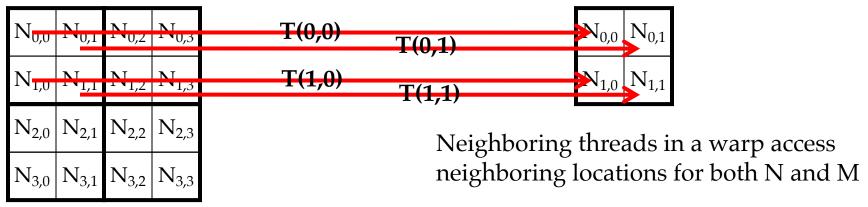

Tiled Multiply

- Break up the execution of the kernel into phases so that the data accesses in each phase are focused on one tile of M and N
- For each tile:
 - Phase 1: Load tiles of M & N into share memory
 - Phase 2: Calculate partial dot product for tile of P

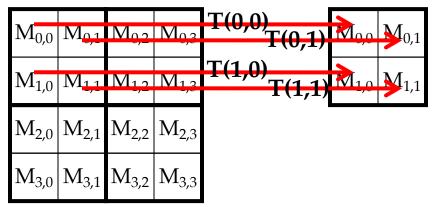

Loading Tiles for Block (0,0)

Shared Memory

$M_{2,0}$	$M_{2,1}$	$M_{2,2}$	$M_{2,3}$

Phase 1: Loading a Tile

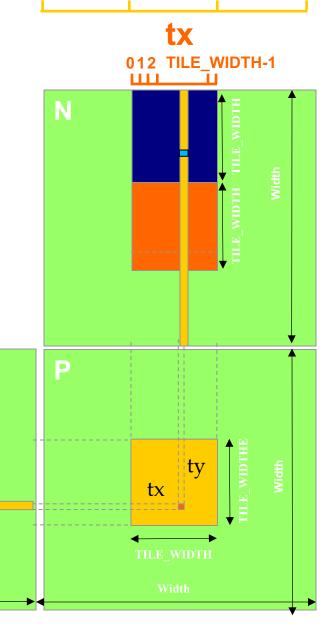

- All threads in the block loads one M element and one N element into shared memory
- Assign the loaded element to each thread such that the accesses within each warp is coalesced (more later).

Loading an Input Tile 0

TILE WIDTH-1

```
tx = threadIdx.x;
ty = threadIdx.y;

subTileM[ty][tx] = M[Row][tx]
subTileN[ty][tx] = N[ty][Col]
```

Loading an Input Tile 1

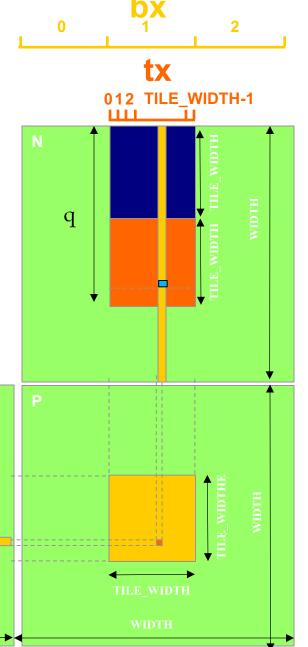

```
012 TILE WIDTH-1
tx = threadIdx.x;
ty = threadIdx.y;
subTileM[ty][tx] = M[Row][1*TILE WIDTH+tx]
subTileN[ty][tx] = N[1*TILE WIDTH+ty][Col]
                               TILE WIDTH-1
                            2
```

Loading an Input Tile q

```
tx = threadIdx.x;
ty = threadIdx.y;
subTileM[ty][tx] = M[Row][q*TILE WIDTH+tx]
subTileN[ty][tx] = N[q*TILE WIDTH+ty][Col]
```

2

TILE WIDTH-1

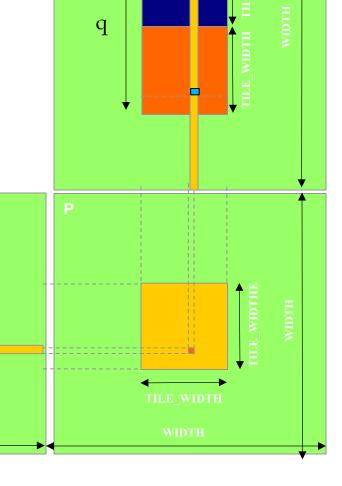

Loading an Input Tile q

However, recall that M and N are dynamically allocated and can only use 1D indexing:

TILE WIDTH

```
tx = threadIdx.x;
ty = threadIdx.y;

subTileM[ty][tx] = M[Row*Width + (q*TILE_WIDTH + tx)]
subTileN[ty][tx] = N[(q*TILE_WIDTH+ty) * Width + Col]
```

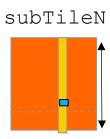

012 TILE WIDTH-1

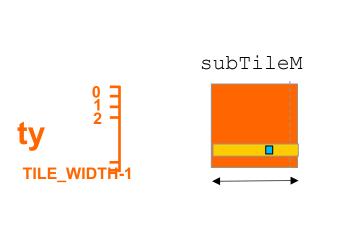

Phase 2: Compute partial product

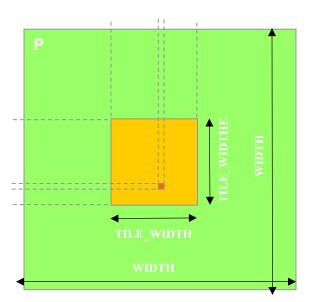

tx
012 TILE_WIDTH-1

To perform the kth step of the product within the tile:

```
PValue += subTileM[ty][k] * subTileN[k][tx];
```

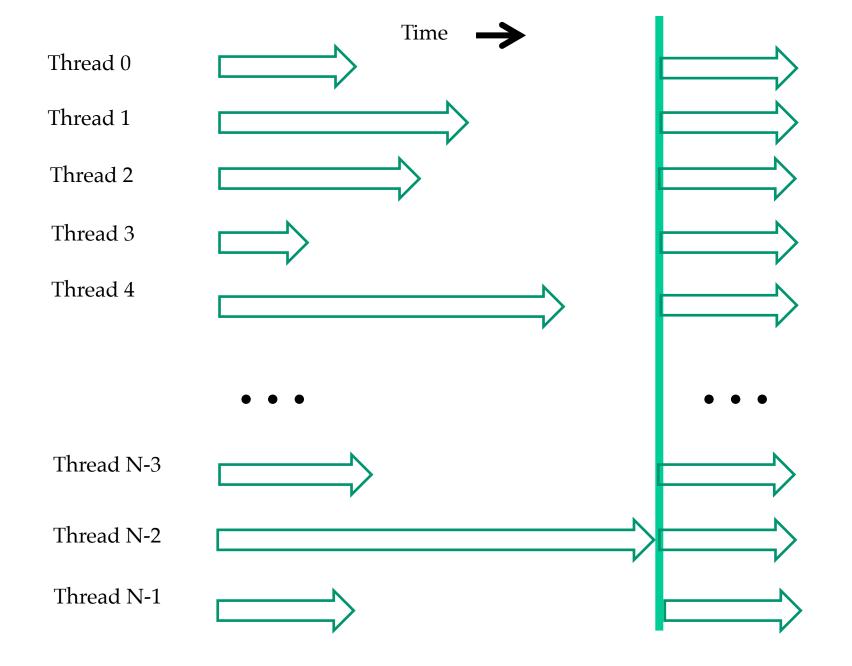

(Incorrect) Tiled Matrix Multiplication Kernel

```
__global__ void MatrixMulKernel(float* M, float* N, float* P, int Width)
     shared float subTileM[TILE WIDTH] [TILE WIDTH];
   shared float subTileN[TILE WIDTH];
3. int bx = blockIdx.x; int by = blockIdx.y;
4. int tx = threadIdx.x; int ty = threadIdx.y;
   // Identify the row and column of the P element to work on
5. int Row = by * TILE WIDTH + ty;
6. int Col = bx * TILE WIDTH + tx;
7. float Pvalue = 0;
   // Loop over the M and N tiles required to compute the P element
   // The code assumes that the Width is a multiple of TILE WIDTH!
8. for (int q = 0; q < Width/TILE WIDTH; ++q) {
      // Collaborative loading of M and N tiles into shared memory
9.
      subTileM[ty][tx] = M[Row*Width + (q*TILE WIDTH+tx)];
      subTileN[ty][tx] = N[(q*TILE WIDTH+ty)*Width+Col];
10.
11.
12.
      for (int k = 0; k < TILE WIDTH; ++k)
13.
          Pvalue += subTileM[ty][k] * subTileN[k][tx];
14.
15. }
16. P[Row*Width+Col] = Pvalue;
```

Bulk Synchronous Steps Based on Barriers

- Sometimes we need all threads to catch up to a certain point in our code before any thread proceeds.
- A barrier is a synchronization point:
 - each thread calls a function to enter barrier;
 - threads block (sleep) in barrier function until all threads have called it
 - after last thread calls the barrier function, all threads continue past the barrier.

Barrier Synchronization

- An API function call in CUDA __syncthreads()
- All threads in the same block must reach the ___syncthreads()
 before any can move on

- Can be used to coordinate tiled algorithms
 - To ensure that all elements of a tile are loaded
 - To ensure that certain computation on elements is complete

Tiled Matrix Multiplication Kernel

```
global void MatrixMulKernel(float* M, float* N, float* P, int Width)
     shared float subTileM[TILE WIDTH][TILE_WIDTH];
   shared float subTileN[TILE WIDTH] [TILE WIDTH] ;
3. int bx = blockIdx.x; int by = blockIdx.y;
4. int tx = threadIdx.x; int ty = threadIdx.y;
   // Identify the row and column of the P element to work on
5. int Row = by * TILE WIDTH + ty;
6. int Col = bx * TILE WIDTH + tx;
7. float Pvalue = 0;
   // Loop over the M and N tiles required to compute the P element
   // The code assumes that the Width is a multiple of TILE WIDTH!
8. for (int q = 0; q < Width/TILE WIDTH; ++q) {
      // Collaborative loading of M and N tiles into shared memory
9.
      subTileM[ty][tx] = M[Row*Width + (q*TILE WIDTH+tx)];
      subTileN[ty][tx] = N[(q*TILE WIDTH+ty)*Width+Col];
10.
11.
      syncthreads();
      for (int k = 0; k < TILE WIDTH; ++k)
12.
13.
          Pvalue += subTileM[ty][k] * subTileN[k][tx];
14.
      syncthreads();
15. }
16. P[Row*Width+Col] = Pvalue;
```

Compare with Basic Matrix Multiply

```
global
void MatrixMulKernel(float *d_M, float *d_N, float *d_P, int Width)
   // Calculate the row index of d P and d M
   int Row = blockIdx.y*blockDim.y+threadIdx.y;
   // Calculate the column index of d P and d N
   int Col = blockIdx.x*blockDim.x+threadIdx.x;
   if ((Row < Width) && (Col < Width)) {
      float Pvalue = 0;
      // each thread computes one element of d P
      for (int k = 0; k < Width; ++k)
          Pvalue += d M[Row*Width+k] * d_N[k*Width+Col];
      d P[Row*Width+Col] = Pvalue;
```

Use of Large Tiles Shifts Bottleneck

- Recall our example GPU: 1,000 GFLOP/s, 150 GB/s mem BW
- 16x16 tiles reuse each operand 16 times
 - reduce global memory accesses by a factor of 16
 - **150GB/s** bandwidth supports (150/4)*16 = 600 **GFLOPS!**
- 32x32 tiles reuse each operand for 32 times
 - reduce global memory accesses by a factor of 32
 - -150 GB/s bandwidth supports (150/4)*32 = 1,200 GFLOPS!
 - Memory bandwidth is no longer the bottleneck!

SM constraints also play a factor

- Shared memory size
 - implementation dependent
 - 64kB per SM in Maxwell (48kB max per block)
- Given TILE_WIDTH of 16 (256 threads / block),
 - each thread block uses2*256*4B = 2kB of shared memory,
 - which limits active blocks to 32;
 - max. of 2048 threads per SM,
 - which limits blocks to 8.

Another Good Choice: 32x32 Tiles

- Given TILE_WIDTH of 32 (1,024 threads / block),
 - each thread block uses2*1024*4B = 8kB of shared memory,
 - which limits active blocks to 8;
 - max. of 2,048 threads per SM,
 - which limits blocks to 2.

Current GPU? Use Device Query

Number of devices in the system

```
int dev_count;
cudaGetDeviceCount( &dev_count);
```

Capability of devices

```
cudaDeviceProp dev_prop;
for (i = 0; i < dev_count; i++) {
          cudaGetDeviceProperties( &dev_prop, i);
          // decide if device has sufficient resources and capabilities
}</pre>
```

cudaDeviceProp is a built-in C structure type

```
- dev_prop.dev_prop.maxThreadsPerBlock
- dev_prop.sharedMemoryPerBlock
- ...
```
